Read the passage given below and answer Q. 97 to 100.

The prevalence and incidence of a disease are among the most fundamental measures in epidemiology. The prevalence of disease is the proportion of the population that has a given disease. This proportion is determined by how many people get the disease and how long they are ill, which is linked to how fast they recover or die. If fewer people get the disease or they recover faster, the prevalence of the disease will go down. However, if survival time with the disease increases without any change in recovery rate, the prevalence will increase. This is a common challenge for many chronic diseases, such as diabetes. Patient care improves so survival time increases, but the disease is not cured and patients may develop complications. The total burden of disease may increase.

Incidence rates represent the number of new cases of disease among the number of susceptible persons in a given location and over a particular span of time. The primary value of incidence rates is in studies of disease etiology, by comparing how the rates vary among different sub groups or with different exposures.

To provide prevalence and incidence rate estimates that are both reliable and generalizable, studies must include a sample large enough to capture most (if not all) cases and sufficiently distributed, both geographically and sociologically, to be representative of the general population with uncommon diseases, including most auto-immune rheumatic diseases, the challenge is multiplied because cases are fewer and harder to find. These factors necessitate surveys of even larger populations to achieve stable estimates, which in turn increase the cost, time and effort involved in executing such studies.

97. In which one of the following situations will the prevalence of a disease in the population increase, all else being constant ?

- (A) If the incidence rate of the disease falls
(B) If survival time with the disease increases
(C) If recovery of the disease is faster
(D) If the population in which the disease is measured increases

98. The study of incidence of a disease is helpful for following reasons :

- disease etiology.
- to compare rates among subgroups.
- to identify number of new cases.
- to study mortality rates.

99. Identify the correct statements :

- A large sample size is needed to arrive at reliable estimates for prevalence and incidence of a disease.
- Rheumatic diseases are evenly distributed among all populations.
- Study of a larger population is not cost-effective and labor intensive.
- Survival time increases with patient care.

Codes :

- (A) c and d (B) a, c and d
(C) b, c and d (D) a only

100. If survival time with the disease increases without any change in recovery rate

- (A) the total burden of disease may decrease
(B) the incidence of disease does not change
(C) the disease prevalence will decrease
(D) the disease prevalence will increase
